A method for client-side document annotation, the method comprising:

 a content provider computer system storing and making accessible an
 original unmodified document:

a central computer system storing and making accessible a current version of a key element list file;

the key element list comprising key element(s) that have corresponding Smart Links that contain executable code to directly link to information that is contextually relevant to a key element;

a client computer system storing Browser Helper Object, a Recognizer Module, an Annotator Module, and a client key element list file;

the Browser Helper Object managing and embodying the key list stored on the client computer system, the Recognizer Module, and the Annotator Module; the Browser Helper Object performing the following:

communicating with the content provider computer system to retrieve the original unmodified document:

communicating with the central computer system to compare the current version of the key element list file on the central computer system with the client key element list file and retrieving the current key element list, when necessary, and updating the client key element list;

executing the Recognizer Module to analyze and parse data in the original unmodified document to recognize if key elements exist in the original unmodified document by comparing the parsed data with key elements from the client key element list:

determining that the Recognizer Module recognizes that the parsed data in the original unmodified document contains key element(s) then executing the Annotator Module to annotate the identified key element(s) in the original unmodified document to include the corresponding Smart Link(s) stored in the client key element list file that corresponds to the recognized key element and thereby creating an annotated document on the client computer system;

displaying, based on the determination steps, the annotated document or the unmodified document.
